## Difference Between Sonogram and Ultrasound

1. A sonogram is a visual image which is the outcome of the process of Ultrasound.
2. Ultrasound involves the usage of soundwaves to generate electrical signals which later on are converted into visual pictures, called sonograms, by a computer.
3. Ultrasound is useful in being able to see the pictures of the internal body, which will ultimately help in diagnosing diseases and infections to cure, from its outcome called Sonograms.
4. Ultrasound is performed through a system including computer, monitor, printer and a handheld transducer while the sonograms are created using the electrical signals by the computer only.
5. Ultrasound is a delicate process using different instruments like transducer etc., whereas sonograms are visual pictures and can also be printed in a physical format.
